Introduction

What are Filesystems?

- Filesystems manage the storage and retrieval of files from storage media.
- Filesystems are an abstraction layer between storage media (SSDs, HDDs, disk drives, even tape drives).
- Filesystems exist on *partitions*, physically contiguous segments of the disk.

Filesystems are Responsible for...

- **Space management:** filesystems allocate and manage space in discrete chunks. Filesystems must keep track of what data is stored at each chunk.
- **Filenames:** identify a storage location in the file system. Can be case sensitive (ext4) or case insensitive (HFS, NTFS).
- **Directories (folders):** group files into separate collections. Modern filesystems allow arbitrary nesting of directories.
- **Metadata:** filesystems store book-keeping information about their contents (e.g. file sizes, last accessed date, owner and permissions, etc.).
- **Access Control:** prevent unauthorized access to files on disk.
- **Data Integrity:** filesystems must be resilient to failure, some are better at this than others.

History of Filesystems

Current Filesystems
